Data Quality Control

Seaglider QC is built in layers, loosely patterned on Argo. The **glider** records raw measurements and does almost no data QC of its own. The **basestation** converts every dive into a per-profile NetCDF file and runs a fully automated QC pass on it, the equivalent of Argo's *real-time* QC. The **scientist** can then review each profile and override the automated result with directives, the equivalent of *delayed-mode* QC.

Source

Paraphrased from the UW *Seaglider Quality Control Manual* (v1.15 with revisions to 2023, shipped as `docs/Seaglider_Quality_Control_Manual.html` in the basestation3 source), the basestation3 code itself (`MakeDiveProfiles.py`, `QC.py`, checked October 2026) and its *Alerts Reference Manual*, the APL-UW IOP *Basestation3 best practices* note and *SGX Documentation*, the 2026 IOP office hours on the flight model and on basestation data processing, and operator correspondence. Where the manual and the code differ, this page follows the code. Defaults change between releases, so check `sg_config_constants()` in `MakeDiveProfiles.py` for your version, and defer to APL-UW IOP.
